

Reclaimed Lumber Intelligence Layer

How the app turns open data and sourced coefficients into a forecast of salvageable lumber, then maps the demand and the ecosystem that decide whether it gets reused.

Open the live app >

The pipeline, end to end

Six stages. Each box feeds the next, and every coefficient carries a citation and a range.

Inside the recovery cascade

One post-war single-detached home: 120 m2 of floor area, built around 1965, mixed demolition practice. Each arrow multiplies by a sourced coefficient.

Coefficients: framing content (McKeever & Phelps, FPL 1994); recovery and condition (Oregon DEQ 2019); denailing and grading (Falk, FPL-RP-650, 2008).

Two-sided ecosystem and demand

Supply is half the story. This side covers the firms that recover and remake wood, and the markets that buy it. The circular value chain runs from generation to resale and loops back.

Firm counts are the national SME census by value-chain step (Light House for ECCC, March 2026; 252 SMEs). Retail leads because it includes 102 Habitat ReStores.

DEMAND LEGAL TODAY

~22M bf

DEMAND IF REUSE ALLOWED

~88M bf

Latent demand runs above current spec-ready supply, so the binding constraint is supply and coordination. The diagnosis below ranks why.

#	Why recoverable wood is not reclaimed	Binds on
1	Structural-reuse code wall (salvaged lumber must be regraded; no code path)	Demand (rules)
2	No forward supply signal, so buyers cannot commit early	Coordination
3	Processing and de-nailing labour cost	Supply
4	Deconstruction costs more and takes longer than demolition	Supply
5	Storage, logistics, and missing grading standards	Supply

Decision: live data or fallback

Coverage sets the band

Coverage	Markets	Band
HIGH	Toronto (live feed)	+/- 10%
MEDIUM	Vancouver, Montreal, Calgary, Edmonton, Ottawa-Gatineau	+/- 25%
LOW	The other 19 CMAs (inferred)	+/- 45%
