

Reclaimed Lumber Intelligence Layer

How the app turns open data and sourced coefficients into a confidence-scored estimate of salvageable lumber across Canada's 25 largest metro regions.

Open the live app > [live dashboard](#)

The pipeline, end to end

Five stages. Each box on the left feeds the next, and every coefficient in the model carries a citation and a plausible range.

Inside the recovery cascade

A worked example: one typical post-war single-detached home (120 m2 of floor area, built around 1965, mixed demolition practice). Each arrow multiplies by a sourced coefficient.

Coefficients: framing content (McKee & McKeever, FPL 1994); recovery 0.30 and condition 0.73 (Oregon DEQ 2019, age-adjusted); denailing 0.70 and grading 0.55 (Falk, FPL-RP-650). Gross wood content including panels and finish is 11,911 bf. Multiply by the city's annual demolitions to scale from one home to a market.

Decision chart: live data or fallback

How the app decides whether a run uses live Toronto data, and how it labels the result.

Coverage tier sets the confidence band

The tier each market lands in decides how wide its Monte Carlo band is. That is the void analysis made quantitative.

Coverage	Which markets	Band
HIGH	Toronto (live permit feed)	+/- 10%
MEDIUM	Vancouver, Montreal, Calgary, Edmonton, Ottawa-Gatineau (real StatCan figures)	+/- 25%
LOW	The other 19 CMAs (inferred from dwellings and rate)	+/- 45%

The band on the demolition count combines with the sampled coefficient ranges in the Monte Carlo, so low-data cities get an honestly wide P10 to P90 spread rather than false precision.

What comes out

Output	Where in the app
National and per-CMA supply, value	Overview, Municipal baseline
5 to 10 year forecast with P10/P50/P90	Forecast & uncertainty
Sensitivity tornado	Forecast & uncertainty
Ecosystem gaps	Ecosystem & gaps
Scenario testing	Sidebar scenario selector
